Diabetes

A disease on the rise

Diabetes is a life-long condition that affects a lot of people, especially in the United States. Among seniors over the age of 60, nearly 1 in 5 have been diagnosed with diabetes. Additionally, 1 in 3 children who were born in the year 2000 will be diagnosed with diabetes at some point in their lifetime. Maintaining healthy blood glucose levels is the most important way to control diabetes. This includes regular testing of glucose levels and understanding how certain foods affect glucose levels in your body. Having high blood glucose levels increases the risk of eye, kidney, nerve, and heart damage.

What causes diabetes? The body uses glucose, a simple sugar, as fuel for performing normal daily functions. Insulin is a hormone that helps the body use or store the blood glucose it gets from food. If your body is unable to make or use insulin properly, you will have high blood glucose levels. There are three types of diabetes: In type 1, which is often diagnosed in childhood, the pancreas is unable to make insulin. In type 2, which is the most common type of diabetes in the United States, the body does not respond well to insulin. The last type of diabetes is gestational diabetes, which is a type of diabetes that only occurs in women during pregnancy.

Seven percent of the U.S. population - about 20.8 million children and adults - are currently living with diabetes. Also, about 6.2 million of those people are not aware that they have the disease.

Who is at risk for diabetes?

Type 1 Diabetes can occur without warning and does not require a family history to be present. The following risk factors are specifically focused on Type 2 Diabetes:

- 45 years of age and older
- Body mass index (BMI) greater than 25
- Family history of type 2 diabetes
- American Indians, Hispanic/Latino Americans, African Americans, Asian Americans and Pacific Islanders
- High blood pressure
- High cholesterol or triglycerides levels
- Physical inactivity

What are the warning signs of diabetes?

How can I control my diabetes?

Make changes to your lifestyle...

Lose weight or maintain a healthy weight. Often, if you lose 5 to 10 pounds, blood glucose levels become easier to control. Usually, your doctor may have specific weight loss goals for you.

Exercise. It can significantly lower blood glucose levels, and increase your body's sensitivity to insulin. This improves your body's ability to use and store glucose.

Monitor your total calorie intake. Your diet should have equal amounts of protein, complex carbohydrates and fats.

Regularly monitor blood glucose levels and track your progress with your healthcare provider.

Take medications as directed. Medications are vital players in blood sugar management.

Manage other disease states. Controlling blood pressure, cholesterol, and other existing medical conditions can all positively influence your diabetic status.

Happy Thanksgiving
